CS 589 Fall 2020

Information Retrieval Evaluation

Retrieval Feedback

Instructor: Susan Liu

TA: Huihui Liu

Stevens Institute of Technology

Information retrieval evaluation

- Last lecture: basic ingredients for building a document search engine
- You graduate and join Bing

Information retrieval evaluation

- How to know
 - If your search engine has outperformed another search engine
 - If your search engine performance has improved compared to last quarter?

Metrics for a good search engine

Return what the users are looking for

• Relevance, CTR

Return results fast

Latency

Users likes to come back

Retention rate

Rank-based measurements

- Binary relevance
 - Precision@K
 - Mean average precision (MAP)
 - Mean reciprocal rank (MRR)
- Multiple levels of relevance
 - Normalized discounted cumulative gain (NDCG)

Precision of retrieved documents

Fraction of retrieved docs that are relevant

$$precision = \frac{\#relevant\&retrieved}{\#retrieved}$$

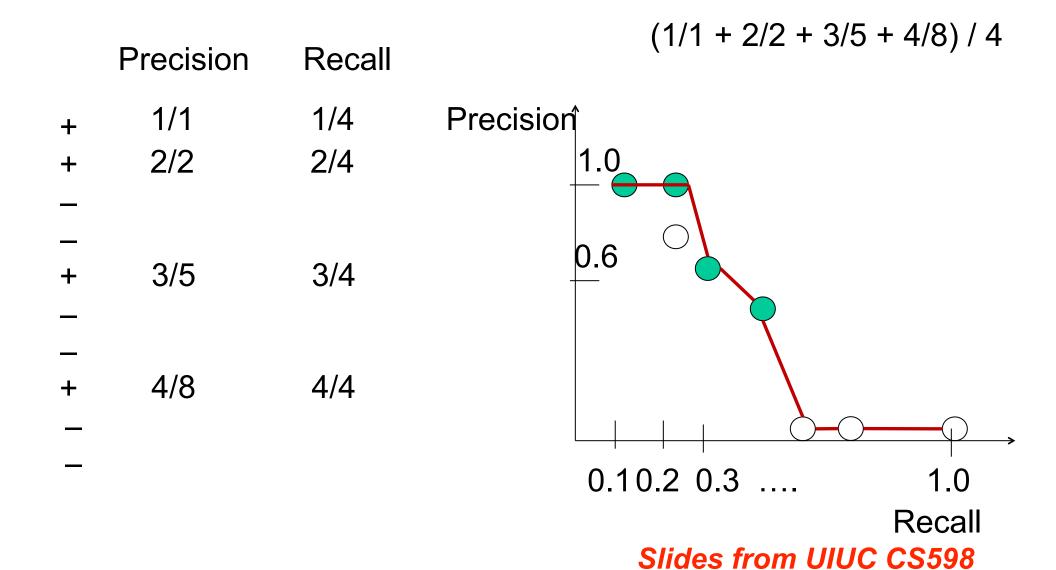

Fraction of relevant documents that are retrieved

$$recall = \frac{\#relevant\&retrieved}{\#relevant}$$

Rank-based measurements

- Binary relevance
 - Precision@K
 - Mean average precision (MAP)
 - Mean reciprocal rank (MRR)
- Multiple levels of relevance
 - Normalized discounted cumulative gain (NDCG)

Precision-recall curve

Mean average precision

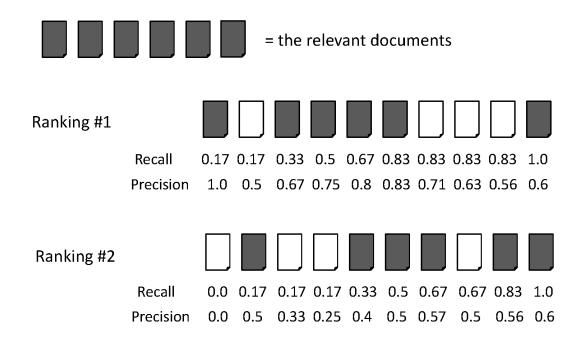

- Consider rank position of each relevant doc
 - K₁, K₂, ... K_R
- Compute Precision@K for each K₁, K₂, ... K_R
- Average <u>precision</u> = average of P@K

Ex:

has AvgPrec of
$$\frac{1}{3} \cdot \left(\frac{1}{1} + \frac{2}{3} + \frac{3}{5}\right) \approx 0.76$$

 MAP is Average Precision across multiple queries/ rankings

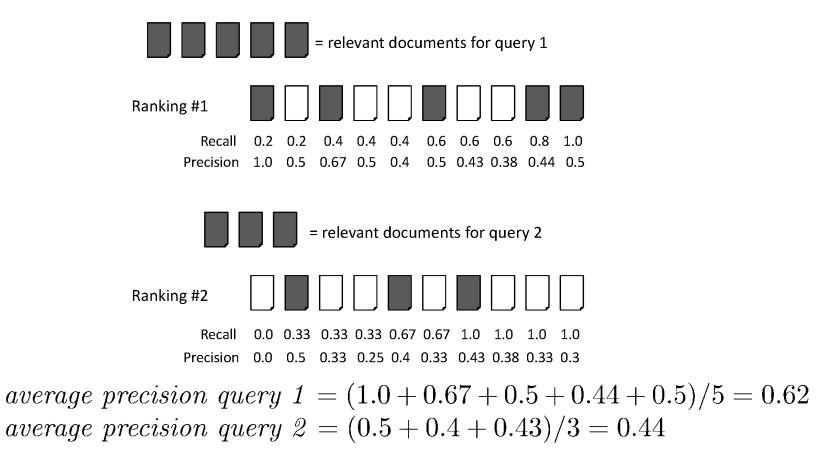

Average precision

Ranking #1:
$$(1.0 + 0.67 + 0.75 + 0.8 + 0.83 + 0.6)/6 = 0.78$$

Ranking #2:
$$(0.5 + 0.4 + 0.5 + 0.57 + 0.56 + 0.6)/6 = 0.52$$

MAP

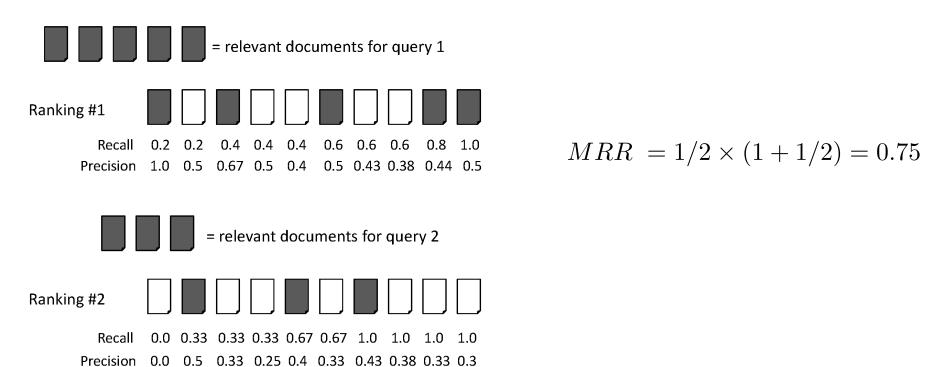

mean average precision = (0.62 + 0.44)/2 = 0.53

Slides from Stanford CS276 11

Mean reciprocal rank

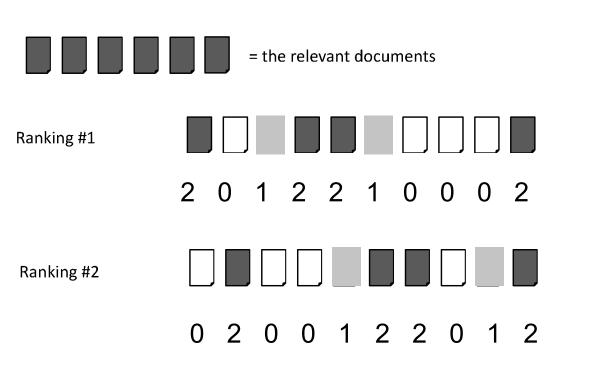

- Measure the effectiveness of the ranked results
 - Assume users are only looking for one relevant document

Beyond binary relevance

- Discounted cumulative gain (DCG)
- Popular measure for evaluating web search and related tasks
- Information gain-based evaluation
 - For each relevant document, the user has gained some information
 - The higher the relevance, the higher gain
 - The gain is discounted when the relevant document appears in a lower position

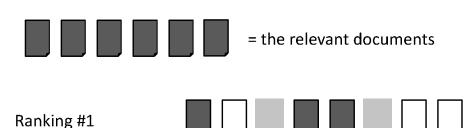

Discounted cumulative gain (DCG)

$$DCG@3 \ query \ 1 = \frac{2^2 - 1}{\log_2 2} + \frac{2^1 - 1}{\log_2 4} + \frac{2^2 - 1}{\log_2 5} = 4.79$$

$$DCG@3\ query\ 2 = \frac{2^2 - 1}{\log_2 3} + \frac{2^1 - 1}{\log_2 6} + \frac{2^2 - 1}{\log_2 7} = 3.34$$

Normalized Discounted cumulative gain (nDCG)

$$0 \ 2 \ 0 \ 0 \ 1 \ 2 \ 2 \ 0 \ 1 \ 2$$

$$IDCG@3\ query\ 1 = \frac{2^2 - 1}{\log_2 2} + \frac{2^2 - 1}{\log_2 3} + \frac{2^2 - 1}{\log_2 4} = 6.39$$

$$IDCG@3\ query\ 2 = \frac{2^2 - 1}{\log_2 2} + \frac{2^2 - 1}{\log_2 3} + \frac{2^2 - 1}{\log_2 4} = 6.39$$

$$nDCG = (4.79/6.39 + 3.34/6.39)/2 = 0.64$$

Relevance evaluation methodology

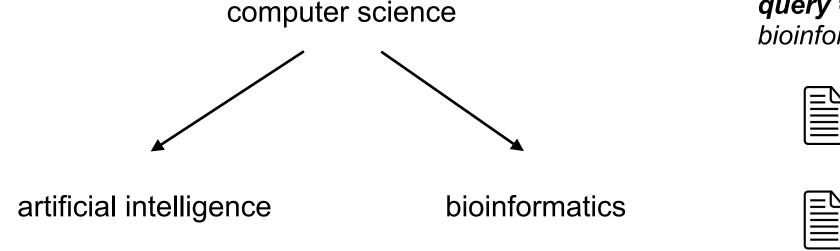

- Offline evaluation:
 - Evaluation based on annotators' annotation
 - TREC conference
 - Cranfield experiments
 - Pooling
 - Evaluation based on user click through logs
- Online evaluation
 - A/B testing

Text REtrieval Conference (TREC)

     Quest
                 about pet therapy programs, descriptions of the circumstances in which
     Microk
                 pet therapy is used, the benefits of this type of therapy, the degree
                 of success of this therapy, and any laws or regulations governing it.
                 </top>
```

The Cranfield experiment (1958)

Imagine you need to help users search for literatures in a digital library, how would you design such a system?

query = "subject = AI & subject = bioinformatics"

system 1: the Boolean retrieval system

The Cranfield experiment (1958)

 Imagine you need to help users search for literatures in a digital library, how would you design such a system?

Document-term matrix

	intelligence	book	the	cat	artificial	dog	business
Doc1	8	1	3	1	0	1	0
Doc2	1	f	0	0	0	0	1
query	1	0		0	1	0	0

query = "artificial intelligence"

bags of words representation

The Cranfield experiment (1958)

- Basic ingredients
 - A corpus of documents (1.4k paper abstracts)
 - A set of 225 queries and their information needs
 - Binary relevance judgment for each (q, d) pair
 - Reuse the relevance judgments for each (q, d) pair

query = "best phone", time = 2012, relevance = 1

Nokia

query = "best phone", time = 202220 relevance = 0

Scalability problem in human annotation

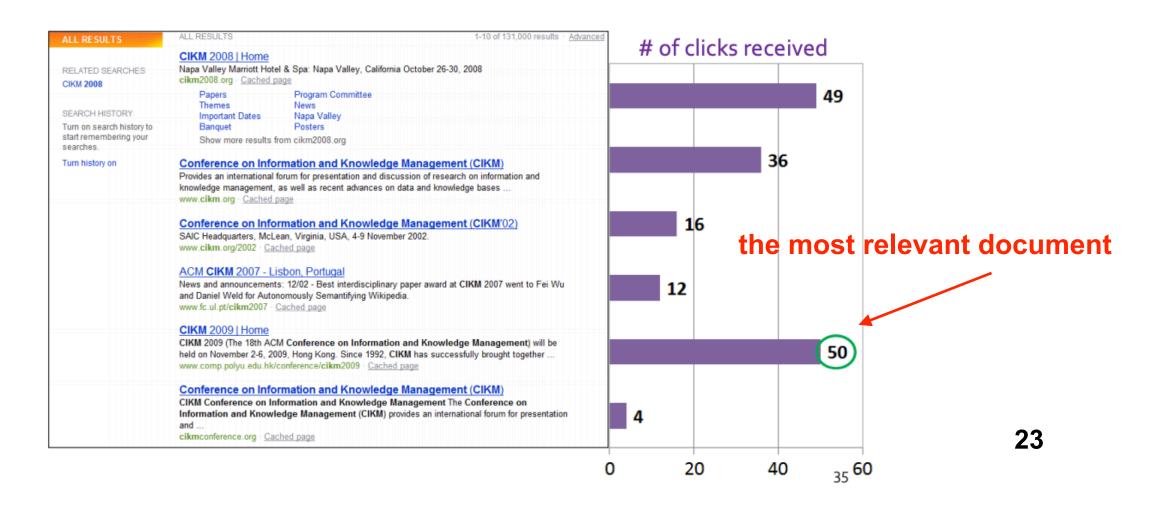

- TREC contains 225 x 1.4k = 315k (query, documents) pairs
- How to annotate so many pairs?

- Pooling strategy
 - For each system, first run the system to get top 100 results
 - Annotate the union of all such documents

- TREC style relevance judgment
 - Explicit relevance judgment
 - Difficult to achieve large scalability
 - Relevance is fixed
- Relevance judgment using user clicks
 - Implicit relevance judgment
 - Effortless relevance judgment at a large scale
 - Relevance is fixed, (assume relevance judgment stays the same upon reranking)

Click logs for "CIKM"

slides from Stanford CS276

- System logs the users engagement behaviors:
 - Time stamp
 - Session id
 - Query id, query content
 - Items viewed by the user (in sequential order)
 - Whether each item has been clicked by the user
 - User's demographic information, search/click history, location, device
 - Dwell time, browsing time for each document
 - Eye tracking information

- Click logs are stored in large tables
- Using SQL to extract a subset of query logs

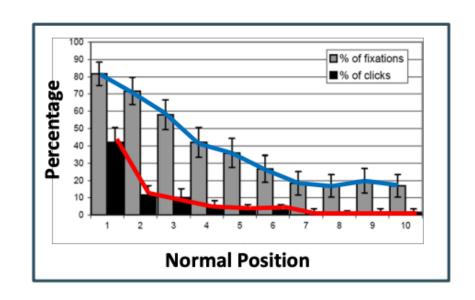

Session Id	Timestamp	Action	Action details				
123457	1388494920	search	Query = 'flawless'				
123457	1388494980	click	Page Id = '755'				
123457	1388495060	reformulation	Query ='flawless beyonce' => Reformulation = 'beyonce'				
123457	1388495115	click	Page Id = '170'				
123458	1388495415	search	Query ='cikm conference'				
123456	1388361661	reformulation	Query ='cikm conference' => Reformulation = '2014'				
123456	1388361720	click	Page Id = "45"				

Online evaluation methodology

- Assumption made by offline evaluation
 - After reranking, relevance judgment stays the same
 - Which is not true...
- Relevance judgment is dynamic, subject to user bias
 - Bias based on positions
 - Preference shifting over time, location
 - Satisficing bias

Position bias [Craswell 08]

- Position bias
 - Higher position receives more attention
 - The same item gets lower click in lower position

Satisficing bias

VS

\$500, 30G

\$550, 20G

\$400, 20G

click probability = 0.5

click probability = 0.4

click probability = 0.5

Online evaluation methodology

- Evaluation by actually having the system deployed and observe user response
 - Less scalable
 - A/B testing

Interleaving

Online evaluation methodology

- Bing has an existing ranking algorithm A
 - Testing algorithm B is better than A
 - Strategy 1: Running A of 1 month, running B for the next month
 - Strategy 2: Running A 50% of the time, B 50% of the time
- Disadvantage with Strategy 1 and 2:
 - If B fails, it will hurts user experience from the B group
- Running B 5% of the time, running A 95% of the time

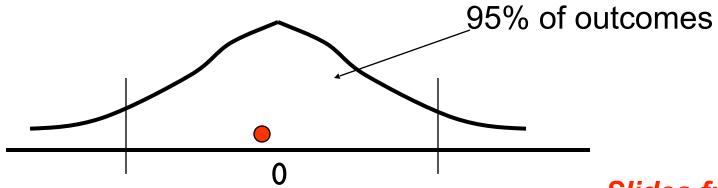

Statistical significance testing

 How sure can you be that an observed difference doesn't simply result from the particular queries you chose?

Experiment 1				Experiment 2			
<u>Query</u>	System A	System B	Query	System A	System B		
1 2 3 4 5 6 7	0.20 0.21 0.22 0.19 0.17 0.20 0.21	0.40 0.41 0.42 0.39 0.37 0.40 0.41	1 2 3 4 5 6 7	0.02 0.39 0.16 0.58 0.04 0.09 0.12	0.76 0.07 0.37 0.21 0.02 0.91 0.46		
Average	e 0.20	0.40	Average	e 0.20	0.40		

Statistical significance testing

Query	System A	System B	Sign Test	<u>Wilcoxon</u>
1	0.02	0.76	+	+0.74
2	0.39	0.07	_	- 0.32
3	0.16	0.37	+	+0.21

Average	0.20	0.40	<i>p</i> =1.0	p=0.9375

Retrieval feedback in session search

query = "best phone"

Does the user prefer lower priced phone, or high end phones? Larger storage, better camera?

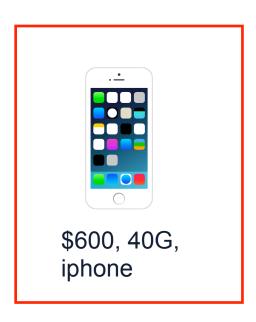

\$400, 20G, Nokia

\$500, 30G, Nokia

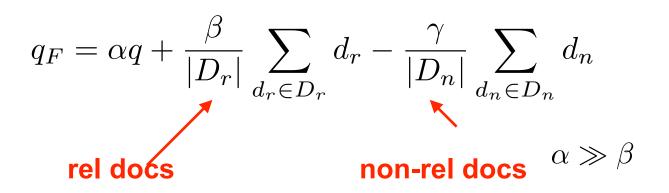

session 2

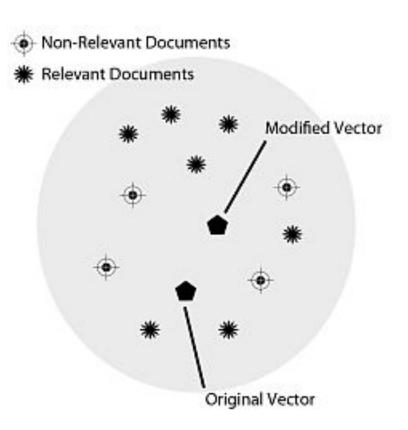

observed click

Rocchio feedback

Feedback for vector-space model

- Rocchio's practical issues
 - Large vocabularies (only consider important words)
 - Robust and effective
 - Requires relevance feedback

Pseudo-relevance feedback

- What if we do not have relevance judgments?
 - Use the top retrieved documents as "pseudo relevance documents"
- Why does pseudo-relevance feedback work?

```
query = "fish tank"
```

Relevance feedback in RSJ model

$$O(rel = 1|q,d) \stackrel{rank}{=} \sum_{w_i=1} \log \frac{\alpha_i(1-\beta_i)}{\beta_i(1-\alpha_i)}$$
 (Robertson & Sparck Jones 76)

$$\alpha_i = p(w_i = 1|q, rel = 1)$$

$$= \frac{count(w_i = 1, rel = 1) + 0.5}{count(rel = 1) + 1}$$

Probability for a word to appear in a relevant doc

$$\beta_i = p(w_i = 0|q, rel = 0)$$

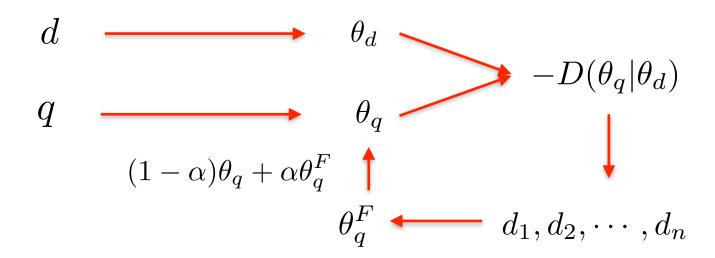

$$= \frac{count(w_i = 0, rel = 0) + 0.5}{count(rel = 0) + 1}$$

Probability for a word to appear in a non-relevant doc

(Pseudo)relevance feedback language model

$$score^{JM}(q,d) = \sum_{w_i, w_i \in d, p(w_i | \hat{\theta}_q)} p(w_i | \hat{\theta}_q) \log \left(1 + \frac{(1 - \lambda)count(w_i, d)}{\lambda p(w_i | C)}\right)$$

$$p(w_i|q) = rac{count(w_i,q)}{|q|}$$
 sparsity
